

Once logged in you will see the following page (be warned, the site layout changes quite frequently, so you might have to do some digging).

The first mistake I made was not checking the region in which I was creating my AWS instance. So I created mine in the USA. Not that this really matters for serving a few webpages, but if speed is important, ensure you select a region closest to you.

You can do this by clicking the current region in the top right hand corner (highlighted in Orange) and select a suitable local region.

We have to choose what we are going to create.

From the top left of the page, select Services, then select **EC2** from the Compute section.

Now we can select some options and launch our virtual server.

Click on the **Launch Instance** button.

A page with different Operating Systems will open.

I am going to use the top option of **Amazon Linux AMI**. It's a Linux system similar to CentOS. There are many choices of OS here, and I have not tried many of them. My intention is to use this server for a bit of testing, and I don't want it to cost me anything, so I am unsure if picking say Windows will incur any costs (I would guess it does). As long as it has a 'Free tier Available' label you should be good to go.

Select **Amazon Linux AMI 64bit** (Blue button on the right hand side of the page.)

Next we have to choose our instance type. This is setting up how many processors (vCPUs) memory, hard disk space etc that we want.

*** DO NOT CLICK Configure and Launch *** There are a lot of options here, but for those of use wanting a free server, there is only one, the **t2micro (Free tier eligible)** so that makes our decision process pretty simple.

Select **Configure Instance Details** from the bottom right of the page.

Before we launch our instance, we can make some changes. Click the **Add Storage** tab.

By default you get a storage area of 8GB, if this is not enough then you can increase it. There is an information box that states (at the time of writing) you can have up to 30GB free. Remember, if you plan to have more than one EC2, you have to split that across them.

I left my configuration at 8GB.

Click the **Add Tags** tab.

You don't have to do this, but if you are going to have a lot of instances, it does become necessary. Just add a name for this instance (I used Test Webserver.)

Click the **Configure Security Group** tab.

You can look at security groups as a firewall. All ports are closed unless you open them. By default port 22 (SSH) is open, or you would have no access to your OS. As this is going to be a web server, I will also open Port 80.

Click **Add Rule** and select **HTTP** as the type. **0.0.0.0/0, ::/0** means accept traffic from any IP Address. For the SSH I would limit that to your own IP (say your work or home IP).
